## **A RARE CASE OF EVISCERATION THROUGH THE ILEOSTOMY IN EMERGENCY SURGERY**

The creation of a bowel stoma has complications in a large number of patients. The risk of stoma complications is related to many factors, including comorbidity, urgent surgery and surgical technique.

Among the complications are infection, mucocutaneous dehiscence, bleeding, necrosis and sinking. Ileostomy evisceration is an anecdotal situation and there are very few published cases in this regard.

To present the case of a 16-year-old woman with Infantile Cerebral Paralysis and diagnosis of Ogilvie Syndrome. Urgent surgery required for a case of intestinal obstruction resistant to conservative treatment. In the first intervention an ischemia of the right colon was evidenced, treated with a right colectomy and terminal ileostomy. The postoperative period complicated with a paralytic ileus with a marked abdominal distension and hydroelectrolytic disorders that were managed conservatively. On the 7th postoperative day, the patient presented a evisceration of small intestine through the ileostomy, with torsion and initial signs of suffering, causing a condition of intestinal obstruction. In the first place, manual reduction is attempted, although it is impossible given the small size of the defect, requiring urgent surgical intervention. In the surgical exploration, the appropriate viability of the loop was verified, continuing with the reduction of the content and closing of the defect with the continuous suture and the new fixation of the ileostomy to the skin.

The patient had a postoperative period without incidents, without local complications, recovering the intestinal transit on the fourth day.
